# Analyze\_ab\_test\_results\_notebook

## December 17, 2020

# 0.1 Analyze A/B Test Results

You may either submit your notebook through the workspace here, or you may work from your local machine and submit through the next page. Either way assure that your code passes the project RUBRIC. Please save regularly.

This project will assure you have mastered the subjects covered in the statistics lessons. The hope is to have this project be as comprehensive of these topics as possible. Good luck!

#### 0.2 Table of Contents

- Section ??
- Section ??
- Section ??
- Section ??

#### ### Introduction

A/B tests are very commonly performed by data analysts and data scientists. It is important that you get some practice working with the difficulties of these

For this project, you will be working to understand the results of an A/B test run by an e-commerce website. Your goal is to work through this notebook to help the company understand if they should implement the new page, keep the old page, or perhaps run the experiment longer to make their decision.

As you work through this notebook, follow along in the classroom and answer the corresponding quiz questions associated with each question. The labels for each classroom concept are provided for each question. This will assure you are on the right track as you work through the project, and you can feel more confident in your final submission meeting the criteria. As a final check, assure you meet all the criteria on the RUBRIC.

```
#### Part I - Probability
```

To get started, let's import our libraries.

```
In [1]: import pandas as pd
    import numpy as np
    import random
    import matplotlib.pyplot as plt
    %matplotlib inline
    #We are setting the seed to assure you get the same answers on quizzes as we set up
    random.seed(42)
```

- 1. Now, read in the ab\_data.csv data. Store it in df. Use your dataframe to answer the questions in Quiz 1 of the classroom.
  - a. Read in the dataset and take a look at the top few rows here:

```
In [2]: df=pd.read_csv('ab_data.csv')
        df.head()
Out[2]:
           user_id
                                                    group landing_page converted
                                     timestamp
           851104 2017-01-21 22:11:48.556739
                                                              old_page
        0
                                                  control
                                                                                0
           804228 2017-01-12 08:01:45.159739
                                                              old_page
                                                                                0
        1
                                                  control
          661590 2017-01-11 16:55:06.154213
                                                treatment
                                                              new_page
                                                                                0
          853541 2017-01-08 18:28:03.143765
                                                treatment
                                                              new_page
                                                                                0
           864975 2017-01-21 01:52:26.210827
                                                  control
                                                              old_page
                                                                                1
```

b. Use the cell below to find the number of rows in the dataset.

```
In [3]: df.shape
Out[3]: (294478, 5)
```

c. The number of unique users in the dataset.

```
In [4]: df['user_id'].nunique()
Out[4]: 290584
```

d. The proportion of users converted.

```
In [5]: df['converted'].mean()
Out[5]: 0.11965919355605512
```

e. The number of times the new\_page and treatment don't match.

f. Do any of the rows have missing values?

```
In [7]: df.info()
```

- 2. For the rows where **treatment** does not match with **new\_page** or **control** does not match with **old\_page**, we cannot be sure if this row truly received the new or old page. Use **Quiz 2** in the classroom to figure out how we should handle these rows.
  - a. Now use the answer to the quiz to create a new dataset that meets the specifications from the quiz. Store your new dataframe in **df2**.

```
In [8]: df1 = df.drop(df[(df.group =="treatment") & (df.landing_page != "new_page")].index)

df2 = df1.drop(df1[(df.group =="control") & (df1.landing_page != "old_page")].index)
```

/opt/conda/lib/python3.6/site-packages/ipykernel\_launcher.py:3: UserWarning: Boolean Series key This is separate from the ipykernel package so we can avoid doing imports until

Out[9]: 0

- 3. Use df2 and the cells below to answer questions for Quiz3 in the classroom.
- a. How many unique user\_ids are in df2?

```
In [10]: df2['user_id'].nunique()
Out[10]: 290584
```

b. There is one **user\_id** repeated in **df2**. What is it?

```
In [11]: df2[df2.duplicated(['user_id'], keep=False)]
```

```
      Out[11]:
      user_id
      timestamp
      group landing_page
      converted

      1899
      773192
      2017-01-09
      05:37:58.781806
      treatment
      new_page
      0

      2893
      773192
      2017-01-14
      02:55:59.590927
      treatment
      new_page
      0
```

c. What is the row information for the repeat **user\_id**?

d. Remove **one** of the rows with a duplicate **user\_id**, but keep your dataframe as **df2**.

- 4. Use **df2** in the cells below to answer the quiz questions related to **Quiz 4** in the classroom.
- a. What is the probability of an individual converting regardless of the page they receive?

```
In [15]: df2['converted'].mean()
Out[15]: 0.11959708724499628
```

b. Given that an individual was in the control group, what is the probability they converted?

c. Given that an individual was in the treatment group, what is the probability they converted?

d. What is the probability that an individual received the new page?

```
In [18]: len(df2.query('landing_page == "new_page"'))/len(df2.landing_page)
Out[18]: 0.5000619442226688
```

e. Consider your results from parts (a) through (d) above, and explain below whether you think there is sufficient evidence to conclude that the new treatment page leads to more conversions.

No, there is not sufficient evidence to say that the new treatment page leads to more conversionss as the probabilities of conversions given that an individual was in the "treatment" group or in the "control" group are almost equel

```
12.04% that received the old_page were converted. 11.88% that received the new_page were conver ### Part II - A/B Test
```

Notice that because of the time stamp associated with each event, you could technically run a hypothesis test continuously as each observation was observed.

However, then the hard question is do you stop as soon as one page is considered significantly better than another or does it need to happen consistently for a certain amount of time? How long do you run to render a decision that neither page is better than another?

These questions are the difficult parts associated with A/B tests in general.

1. For now, consider you need to make the decision just based on all the data provided. If you want to assume that the old page is better unless the new page proves to be definitely better at a Type I error rate of 5%, what should your null and alternative hypotheses be? You can state your hypothesis in terms of words or in terms of  $p_{old}$  and  $p_{new}$ , which are the converted rates for the old and new pages.

```
H0: p_{new} = < p_{old}
```

**H1:**  $p_{new} > p_{old}$  2. Assume under the null hypothesis,  $p_{new}$  and  $p_{old}$  both have "true" success rates equal to the **converted** success rate regardless of page - that is  $p_{new}$  and  $p_{old}$  are equal. Furthermore, assume they are equal to the **converted** rate in **ab\_data.csv** regardless of the page.

Use a sample size for each page equal to the ones in **ab\_data.csv**.

Perform the sampling distribution for the difference in **converted** between the two pages over 10,000 iterations of calculating an estimate from the null.

Use the cells below to provide the necessary parts of this simulation. If this doesn't make complete sense right now, don't worry - you are going to work through the problems below to complete this problem. You can use **Quiz 5** in the classroom to make sure you are on the right track.

a. What is the **conversion rate** for  $p_{new}$  under the null?

b. What is the **conversion rate** for  $p_{old}$  under the null?

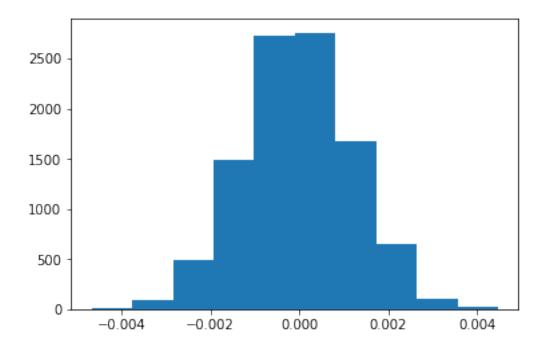

0.119597087245

c. What is  $n_{new}$ , the number of individuals in the treatment group?

```
In [21]: n_new=df2.query('group == "treatment"').shape[0]
         print(n_new)
145310
  d. What is n_{old}, the number of individuals in the control group?
In [22]: n_old=len(df2.query('group == "control"'))
          n_old
Out[22]: 145274
  e. Simulate n_{new} transactions with a conversion rate of p_{new} under the null. Store these n_{new} 1's
     and 0's in new_page_converted.
In [23]: new_page_converted=np.random.binomial(1,p_new,n_new)
         new_page_converted.mean()
Out [23]: 0.12258619503131236
  f. Simulate n_{old} transactions with a conversion rate of p_{old} under the null. Store these n_{old} 1's
     and 0's in old_page_converted.
In [24]: old_page_converted=np.random.binomial(1,p_old,n_old)
          old_page_converted.mean()
Out [24]: 0.12015226399768712
  g. Find p_{new} - p_{old} for your simulated values from part (e) and (f).
In [25]: p_diff = new_page_converted.mean() - old_page_converted.mean()
         p_diff
Out [25]: 0.0024339310336252418
  h. Create 10,000 p_{new} - p_{old} values using the same simulation process you used in parts (a)
     through (g) above. Store all 10,000 values in a NumPy array called p_{diffs}.
In [26]: p_diffs=[]
         for _ in range (10000):
              new_page_converted=np.random.binomial(1,p_new,n_new)
              old_page_converted=np.random.binomial(1,p_old,n_old)
              p_diffs.append(new_page_converted.mean()-old_page_converted.mean())
         p_diffs=np.array(p_diffs)
```

In [27]: plt.hist(p\_diffs);

i. Plot a histogram of the **p\_diffs**. Does this plot look like what you expected? Use the matching problem in the classroom to assure you fully understand what was computed here.

j. What proportion of the **p\_diffs** are greater than the actual difference observed in **ab\_data.csv**?

Out [28]: 0.9013999999999998

k. Please explain using the vocabulary you've learned in this course what you just computed in part **j**. What is this value called in scientific studies? What does this value mean in terms of whether or not there is a difference between the new and old pages?

## Answer

- obs\_diff represents the difference between converted rates of new page and old page, based on our dataset.
- p\_diffs represents the simulated difference between converted rates of new page and old page, based on 10,000 simulated samples.
- The p-value was calculated by computing the proportion of p\_diffs that are greater than obs\_diff observed in our dataset.
- with a p-value of 0.9048, the difference in the conversion rate for the control and treatment groups does NOT appear to be significant. Since the p-value is far greater than the typical *α* level of 0.05 in business studies. As such, we would fail to reject the null hypothesis and keep on the old page.

l. We could also use a built-in to achieve similar results. Though using the built-in might be easier to code, the above portions are a walkthrough of the ideas that are critical to correctly thinking about statistical significance. Fill in the below to calculate the number of conversions for each page, as well as the number of individuals who received each page. Let n\_old and n\_new refer the the number of rows associated with the old page and new pages, respectively.

In [29]: import statsmodels.api as sm

norm.cdf(z\_score)

Out [31]: 0.094941687240975514

In [32]: norm.ppf(1-(0.05/2))

Out [32]: 1.959963984540054

```
convert_old = df2.query('landing_page == "old_page"')['converted'].sum()
         convert_new = df2.query('landing_page == "new_page"')['converted'].sum()
         n_old = len(df2.query('landing_page == "old_page"'))
         n_new = len(df2.query('landing_page == "new_page"'))
         convert_old,convert_new,n_old,n_new
/opt/conda/lib/python3.6/site-packages/statsmodels/compat/pandas.py:56: FutureWarning: The panda
  from pandas.core import datetools
Out [29]: (17489, 17264, 145274, 145310)
 m. Now use stats.proportions_ztest to compute your test statistic and p-value. Here is a
    helpful link on using the built in.
In [30]: z_score, p_value = sm.stats.proportions_ztest([convert_new, convert_old], [n_new, n_old
         print ('The z_score = ',z_score)
         print('The p_value = ', p_value )
The z_{score} = -1.31092419842
The p_{value} = 0.905058312759
In [31]: from scipy.stats import norm
```

n. What do the z-score and p-value you computed in the previous question mean for the conversion rates of the old and new pages? Do they agree with the findings in parts j. and k.?

#### answer

- We found out that the z-score of -1.31092419842 which is less than the critical value of 1.959963984540054. we fail to reject the null hypothesis (the new page is butter than old page).
- yes they agree with the findings in parts j. and k because p\_value greater than alpha.

### Part III - A regression approach

- 1. In this final part, you will see that the result you achieved in the A/B test in Part II above can also be achieved by performing regression.
  - a. Since each row is either a conversion or no conversion, what type of regression should you be performing in this case?

# **Logistic Regresion**

b. The goal is to use **statsmodels** to fit the regression model you specified in part **a.** to see if there is a significant difference in conversion based on which page a customer receives. However, you first need to create in df2 a column for the intercept, and create a dummy variable column for which page each user received. Add an **intercept** column, as well as an **ab\_page** column, which is 1 when an individual receives the **treatment** and 0 if **control**.

```
In [33]: df2['intercept']=1
        df2['ab_page'] = pd.get_dummies(df['landing_page'])['new_page'] # means Use the 1 for ne
        df2.head()
Out [33]:
           user_id
                                                  group landing_page converted \
                                    timestamp
            851104 2017-01-21 22:11:48.556739
                                                control
                                                            old_page
                                                                             0
            804228 2017-01-12 08:01:45.159739
        1
                                                control
                                                            old_page
                                                                             0
        2 661590 2017-01-11 16:55:06.154213 treatment
                                                            new_page
                                                                             0

e. What is the p-value associated with ab\_page? Why does it differ from the value you found in Part II? Hint: What are the null and alternative hypotheses associated with your regression model, and how do they compare to the null and alternative hypotheses in Part II?

#### Answer - The p-value associated with ab\_page is 0.1899 - logistic regression hypotheses: H0: = H1: !=

f. Now, you are considering other things that might influence whether or not an individual converts. Discuss why it is a good idea to consider other factors to add into your regression model. Are there any disadvantages to adding additional terms into your regression model?

#### Answer

- Yes, it is a good idea to consider other factors is a good idea as these factors may contribute
  to significance of our test results and leads to more accurate decisions.
- The disadvantage of adding additional terms of the regression model is whatever the number of the factors in our model we may miss the most important factor.
- g. Now along with testing if the conversion rate changes for different pages, also add an effect based on which country a user lives in. You will need to read in the **countries.csv** dataset and merge together your datasets on the appropriate rows. Here are the docs for joining tables.

Does it appear that country had an impact on conversion? Don't forget to create dummy variables for these country columns - **Hint: You will need two columns for the three dummy variables.** Provide the statistical output as well as a written response to answer this question.

```
In [36]: countries_df = pd.read_csv('./countries.csv')
         df_new = countries_df.set_index('user_id').join(df2.set_index('user_id'), how='inner')
         df new.head()
Out[36]:

p\_value of UK,US (0.0740,0.1295) are larger than 0.05, so non of these varaibles have significant p\_value.

h. Though you have now looked at the individual factors of country and page on conversion, we would now like to look at an interaction between page and country to see if there significant effects on conversion. Create the necessary additional columns, and fit the new model.

Provide the summary results, and your conclusions based on the results.

```

#### 0.2.1 Conclusions

11 11 11

• AT conclusions from using different techniques we found that we will accept the null hypotheses and reject the alternative hypothese So we will keep the old page.

# ## Finishing Up

Congratulations! You have reached the end of the A/B Test Results project! You should be very proud of all you have accomplished!

**Tip**: Once you are satisfied with your work here, check over your report to make sure that it is satisfies all the areas of the rubric (found on the project submission page at the end of the lesson). You should also probably remove all of the "Tips" like this one so that the presentation is as polished as possible.

### 0.3 Directions to Submit

Before you submit your project, you need to create a .html or .pdf version of this note-book in the workspace here. To do that, run the code cell below. If it worked correctly, you should get a return code of 0, and you should see the generated .html file in the workspace directory (click on the orange Jupyter icon in the upper left).

Alternatively, you can download this report as .html via the **File > Download as** submenu, and then manually upload it into the workspace directory by clicking on the orange Jupyter icon in the upper left, then using the Upload button.

Once you've done this, you can submit your project by clicking on the "Submit Project" button in the lower right here. This will create and submit a zip file with this .ipynb doc and the .html or .pdf version you created. Congratulations!
